

The EAP-TLSv1.3 connection behavior

The latest Transport Layer Security (TLS) 1.3 was released in August 2013. The arrival of this new version, has brought some exciting new features.

1 Burning Questions!

1. Will the PSK be common for all the devices?
2. Will the key renegotiation be a part of TLS1.3 architecture, or are we supposed to do something else?
3. Starting point of implementation. *wpa_supplicant* or *hostap*? At what point will we deviate from standard EAP-TLS (purely in implementational sense)?
